1 Overview

[Download PDF Version](#)

What Is the Issue?

Federal datasets play an important role in supporting research across a range of disciplines. Measuring how these datasets are used can help evaluate their impact and inform future data investments. Agencies like the US Department of Agriculture (USDA) track how their datasets are referenced in research papers and disseminate data usage statistics through platforms like [DemocratizingData.ai](#) and [NASS's 5's Data Usage Dashboard](#). These tools rely on identifying dataset mentions in published research. Beyond reporting usage volume, this type of analysis can also provide information about the research topics where federal datasets are applied. This helps characterize their disciplinary reach, including use in areas such as food security, nutrition, and climate, which are inherently multidisciplinary. It may also help identify alternative datasets and methods that researchers use to study similar questions across fields.

The process of identifying dataset mentions in academic research output requires the use of **citation databases**. However, different databases curate content (i.e., research output) in different ways - some focus on peer-reviewed journals while others include preprints and technical reports. Tracking dataset usage requires developing methods that scan publication text for dataset mentions. The accuracy of dataset tracking depends on the scope of research output we can access and analyze. Not to mention, dataset tracking requires reliable citation data from citation databases.

This report presents a methodology for identifying dataset mentions in research publications across various citation databases. In doing so, we compare publication, journal, and topic coverage across Scopus, OpenAlex, and Dimensions [forthcoming] as primary sources. The purpose is to establish a consistent set of statistics for comparing results and evaluating differences in dataset tracking across citation databases. This allows for insights into how publication scope and indexing strategies influence dataset usage statistics.

What Did the Study Find?

Main Finding: Accurate dataset tracking relies heavily on how publications are indexed across citation databases. For two citation databases – Scopus and OpenAlex – carefully constructed seed corpora were needed to track dataset mentions.

Specific Results from Database Comparison:

- After deduplication, the number of distinct authors decreased by XX% in Scopus and XX% in OpenAlex, indicating significant duplicate entries in the raw data

- Institutional coverage was broader in XX, with XX% more institutions represented compared to XX
- Analysis revealed XX major themes in USDA dataset usage, with ?? and ?? being the most prominent
- Minority-Serving Institutions (MSIs) represented only XX% of institutional users, highlighting opportunities for broader engagement

How Was the Study Conducted?

The **three** citation databases we are comparing are Elsevier’s Scopus, OurResearch’s OpenAlex, and Digital Science’s Dimensions.ai. **Scopus** charges for access to its citation database. It focuses on peer-reviewed literature and provides metadata about authors, institutions, and citations for academic journals. **OpenAlex**, an open-source platform, offers free metadata access. It covers both traditional academic publications and other research outputs like preprints and technical reports. **Dimensions**, developed by Digital Science, offers a hybrid model that provides both free and subscription-based access to its citation database. Unlike Scopus, which primarily indexes peer-reviewed journal articles, and OpenAlex, which emphasizes open-access content, Dimensions aggregates a broad spectrum of research outputs, including journal articles, books, clinical trials, patents, datasets, and policy documents. It integrates citation data with funding information, making it a useful tool for assessing the impact of research beyond traditional academic publishing.

How Can These Materials Be Used?

Our methodology provides a systematic approach for assessing citation databases’ strengths and limitations in tracking dataset usage across research papers. We developed procedures for:

- Identifying publication coverage across citation databases
- Cross-referencing publications between datasets
- Deduplicating publication records
- Analyzing research themes and institutional representation

The methodology produced these reusable components:

- Code repository for data cleaning and standardization
- Crosswalk table structure linking Scopus and OpenAlex publication records and institutions
- Data schemas by citation database
- Standardized institution tables using IPEDS identifiers

The methods described can be applied to evaluate other citation databases such as Web of Science, Crossref, and Microsoft Academic, to name a few.

2 Data Collection

The Census of Agriculture, produced by the USDA National Agricultural Statistical Services (NASS), provides information on U.S. farming operations, including production practices and land use. This dataset is used as a case study in this report to systematically compare the coverage, overlap, and differences in publications indexed by the two citation databases. The Census of Agriculture (also referred to as the “Ag Census”) is selected for its frequent use in agricultural and economic research, making it an ideal dataset for assessing differences in publication coverage between Scopus and OpenAlex.

To compare coverage across the two citation databases, publications that mention the Ag Census must first be identified. The methods used to identify dataset mentions in Scopus and OpenAlex are described below.

2.1 Scopus Approach

The first citation database used is Scopus, a publication catalog managed by Elsevier. Ideally, direct Scopus API access would have been used to query full publication text for mentions of the Census of Agriculture. However, the project did not have access to the Scopus API. Only Elsevier, serving as a project partner, was able to execute queries within the Scopus environment. Consequently, the dataset mention search relied on outputs provided by Elsevier rather than independent querying.

Because of these constraints, a seed corpus approach was applied. First, Elsevier matched the names and aliases of selected datasets, including the Census of Agriculture, against full-text records available through ScienceDirect and reference sections of Scopus publications published between 2017 and 2023. This initial step identified journals, authors, and topics most likely to reference the Ag Census. A targeted search corpus was then constructed, narrowing the scope to approximately 1.45 million publications.

Several methods were used to identify mentions of USDA datasets in Scopus publications. First, a reference search was conducted, using exact-text matching across publication reference lists to capture formal citations of datasets. Second, full-text searches were performed using machine learning models applied to publication bodies, identifying less formal mentions of datasets. Third, machine learning routines developed through the 2021 Kaggle competition were applied to the full-text corpus to improve detection of dataset mentions, including instances where references were indirect or less structured. Details about the three machine learning models used are available [here](#).

Because direct access to full publication text was not available, Elsevier shared only the extracted snippets and limited metadata. Manual validation, aided by the use of keyword flags (e.g., “USDA,” “NASS”), confirmed whether identified mentions accurately referred to the Census of Agriculture. To manage validation costs, only publications with at least one U.S.-based author were reviewed.

Full documentation of the Scopus search routine, including query construction and extraction procedures, is available at the project’s [report website](#).

2.2 OpenAlex Approach

The second citation database used is OpenAlex, an open catalog of scholarly publications. OpenAlex offers public access to metadata and, when available, full-text content for open-access publications through its [API](#). Unlike Scopus, which provides controlled access to licensed content, OpenAlex indexes only publications that are openly available or for which open metadata has been provided by publishers.

For OpenAlex, two approaches were used to identify publications referencing the Census of Agriculture. The first approach relied on a full-text search across OpenAlex publication records. The second approach applied a seed corpus methodology, similar to the strategy used for Scopus, to address limitations observed in the initial full-text search.

2.2.1 Full-Text Search Approach

The methodology for collecting mentions of USDA datasets in OpenAlex relied on constructing search queries that combined dataset “aliases” and associated “flag terms” within the text of scholarly works. Dataset aliases represented alternative ways researchers refer to a dataset, such as variations on the Census of Agriculture’s official name. Flag terms represented the institutions or agencies responsible for maintaining the dataset. The combination of dataset alias and flag terms ensured that retrieved publications made an explicit connection to the correct data source. A mention was recorded only if at least one alias and one flag term appeared in the same publication, thereby increasing the likelihood of capturing genuine dataset references rather than incidental matches to individual words.¹

To implement these searches efficiently, the OpenAlex API was accessed using the `pyalex` Python package.²

Search queries were constructed based on OpenAlex’s public API documentation, using both the “[Filter Works](#)” and “[Search Works](#)” endpoints. Filtering parameters were applied to restrict results to English-language publications, published after 2017, classified as articles or reviews, and available through open-access sources.

¹Initial drafts of the query incorrectly included terms like “NASS” and “USDA” in the alias list. This was corrected to ensure that aliases strictly referred to dataset names, and flag terms referred to organizations.

²`Pyalex` is an open-source library designed to facilitate interaction with the OpenAlex API; see <https://help.openalex.org/hc/en-us/articles/27086501974551-Projects-Using-OpenAlex> for more information. The package manages request formatting and automates compliance with OpenAlex’s “polite pool” rate limits, which restrict the number of requests per minute and impose backoff delays. Pyalex introduced automatic pauses between requests, with a default `retry_backoff_factor` of 100 milliseconds, to ensure stable and continuous retrieval. This setup enabled systematic querying while adhering to OpenAlex’s usage policies.

Boolean logic was used to define the text search structure. For the Census of Agriculture, the query grouped several dataset aliases, including “Census of Agriculture,” “USDA Census of Agriculture,” “Agricultural Census,” and “USDA Census.” These aliases were combined using an OR operator. Separately, flag terms including “USDA,” “U.S. Department of Agriculture,” “United States Department of Agriculture,” “NASS,” and “National Agricultural Statistics Service” were also grouped using an OR operator. The final query ensured that both an alias and a flag term appeared by connecting the two groups with an AND operator:

```
(“NASS Census of Agriculture” OR “Census of Agriculture” OR “USDA Census of Agriculture” OR “Agricultural Census” OR “USDA Census” OR “AG Census”) AND (USDA OR “US Department of Agriculture” OR “United States Department of Agriculture” OR NASS OR “National Agricultural Statistics Service”)
```

This structure required that each publication mention both a recognized variant of the Census of Agriculture name and a reference to the institution responsible for producing it.

Publications matching the query were returned in JSON format, based on the OpenAlex “[Work object](#)” schema. Each record included metadata fields such as: - `display_name` (publication title) - `authorships` (authors and affiliations) - `host_venue.display_name` (journal) - `doi` (digital object identifier) - `concepts` (topics) - `cited_by_count` (citation counts) - `type` (publication type, e.g., “article”, “book-chapter”) - `publication_year` (year article was published) - `language` (language, English only) - `is_oa` (open access)

Although a range of publication types were retrieved—including articles, book chapters, dissertations, preprints, and reviews—approximately 80–85 percent were classified as articles. To standardize the dataset for downstream analysis, results were filtered during the search process to retain only records identified as `type = article`. This step removed preprints and non-final versions of works, supporting a more standardized analysis of dataset mentions in peer-reviewed literature.

The code used to implement this querying and filtering process is publicly available [here](#).

2.2.1.1 Limitations of Full-Text Approach

Although the OpenAlex API provides full-text search capabilities, limitations in how publication content is ingested and indexed introduce challenges for identifying dataset mentions accurately.

OpenAlex receives publication text through two primary ingestion methods: PDF extraction and [n-grams delivery](#). In the PDF ingestion method, OpenAlex extracts text directly from the article PDF. However, the references section is not included in the searchable text. References are processed separately to create citation pointers between scholarly works, meaning that mentions of datasets appearing only in bibliographies are not discoverable through full-text search.

In the n-grams ingestion method, OpenAlex does not receive the full article text. Instead, it receives a set of extracted word sequences (n-grams) from the publisher or author. These n-grams represent fragments of text—typically short sequences of one, two, or three words—which are not guaranteed to preserve full continuous phrases. As a result, complete dataset names may be broken apart or omitted, reducing the likelihood that search queries match the intended aliases.

These ingestion and indexing limitations affect the completeness of results when relying solely on OpenAlex full-text search. Mentions of the Census of Agriculture and other USDA datasets that appear either exclusively in references or are fragmented within n-grams may be missed. To address these limitations, an alternative search strategy was developed based on constructing a filtered seed corpus of publications for local full-text analysis.

2.2.2 Seed Corpus Approach

To address limitations in OpenAlex’s full-text indexing methods, a seed corpus approach was applied. The objective was to create a filtered set of publications for local text search to better capture mentions of the Census of Agriculture and related USDA datasets.

To construct the seed corpus, publications were filtered based on several criteria:

- Language: English
- Publication Year: Post-2017
- Publication Type: Articles and reviews
- Open Access Status: Open-access publications only

Filtering was further refined by selecting publications associated with high-relevance topics (Table 1) lists the top 25 topics), top publishing journals (Table 2) lists the top 25 journals), and U.S.-affiliated authors (Table 3) lists the top 25 authors).

Each table presents two key columns to help interpret the selection process. The First Run Count refers to the number of publications linked to each entity (whether a topic, journal, or author) based on metadata from OpenAlex’s full-text search feature. This count reflects how often USDA datasets were mentioned within the full text of publications associated with a particular entity. The OpenAlex Total Count represents the total number of publications linked to that entity in the broader OpenAlex database, without applying any filters related to dataset mentions.

To create a more focused and manageable search corpus, we selected the top 25 entities in each category based on their First Run Count. This approach prioritizes journals, topics, and authors where USDA datasets are most frequently mentioned in the full text, which we interpret as being more representative of actual research activity involving these datasets. It also substantially reduces the workload by limiting the number of publications that need to be retrieved and processed.

Choosing this approach has a few important implications. First, it likely increases the relevance of the resulting corpus by concentrating on publications where USDA data are actively cited or discussed, rather than simply associated with a broader research area. Second, it helps avoid the need to download and process an unmanageable number of PDFs—estimated at around 1.7 million if all identified entities were included. However, this method may introduce some selection bias by favoring entities with higher immediate visibility in the first search pass. Some relevant but less frequently mentioned entities might be excluded, meaning that while efficiency improves, full comprehensiveness is slightly sacrificed. Overall, this tradeoff supports a practical balance between depth and feasibility in building the final dataset.

The resulting seed corpus contained approximately 1,774,245 (**CHECK WITH RAFAEL**) unique publications. An initial download of full-texts achieved a success rate of approximately 35%, corresponding to an estimated 625,000 accessible full texts. Local full-text searches were planned using this subset to improve detection of dataset mentions beyond what was possible through OpenAlex’s built-in search functions.

While the seed corpus approach allowed more targeted retrieval, limitations remain. Full-text download success was constrained by incomplete or inaccessible open-access links, and processing the entire corpus was computationally intensive. Future efforts may require distributed processing or refined selection criteria to further improve efficiency.

Results from both methods are compared to assess differences in dataset mention detection across approaches.

3 Results

3.1 Publication Coverage

An objective of this report is to understand differences in publication coverage across Scopus and OpenAlex. Specifically, we ask: (1) how many and which publications referencing the Ag Census appear in each citation database, and (2) how many and which journals publishing these articles overlap between the two sources. In addition, this analysis aims to determine whether the different search approaches used to find dataset mentions in OpenAlex publications—the full-text search versus a seed-corpus approach—produce substantially different coverage.

This section presents two sets of results. In both cases, a seed-corpus approach is used to identify Ag Census publications in Scopus. We then compare these results to (i) publications identified through a full-text search in OpenAlex and (ii) publications identified using a seed-corpus approach in OpenAlex.

3.1.1 Method 1 (Full Text Search)

The first comparison looks at publication and journal coverage between the Scopus (using the seed-corpus method) and OpenAlex (using the full-text search). The results describe how many publications mention the Ag Census in each database and evaluates the degree of overlap between them.

Table 1 displays the coverage of publications that referenced the Ag Census data. The table distinguishes between results that appear in both databases (column 1), only in OpenAlex (column 2), and only in Scopus (column 3). Column 4 is a total of all distinct publications or journals across both databases. The first row reports the number of individual publications found in each category. The unit of analysis is at the publication level. The second row reports the number of journals that include the Ag Census publications, again broken out by their appearance in one or both datasets. The unit of analysis is at the journal level.

ADD TABLE 1 HERE

The main takeaway from Table 1 is that there is little overlap in publications and journals between the two databases when using OpenAlex’s full-text search. According to this table, there are 5,473 unique publications referencing the Ag Census across both citation databases, appearing in 2,686 unique journals, identified by their ISSNs. The number of overlapping publications is 505 (9.23%), with the majority of publications referencing Ag Census are picked up only by Scopus (4,207 or 76.87%), and a smaller share is identified only in OpenAlex (761 or 13.9%).

Journal coverage shows a similar pattern. Of the journals that include at least one Ag Census publication, 247 (9.2%) are shared between the two databases, 2,362 (87.9%) are found only in Scopus, 77 (2.9%) only in OpenAlex.

These results show that the coverage of publications mentioning the Ag Census and the journals in which they are found is much more extensive in Scopus, and suggest that OpenAlex’s full-text search along may miss many dataset mentions.

3.1.2 Method 2 (Seed Corpus Approach)

Based on the pattern observed from the full-text search in OpenAlex, the differences likely arise, at least in part, from limitations in how OpenAlex processes and indexes text. Specifically, we found that OpenAlex’s full-text search does not index references as searchable text—they are stored as pointers, not included in the searchable body of the publication. In addition, n-gram-level metadata that might capture mentions of the Ag Census outside the main text was not accessible for the full set of publications. To address these limitations and create a more consistent comparison with Scopus, we applied a seed-corpus approach to OpenAlex, targeting a curated set of authors, journals, and topics associated with Ag Census use.

While this method can overcome the limitations of the OpenAlex full-text search, it is computationally more intensive. To limit the cost of the search corpus method, a list of the top authors, topics, and journals is provided, as described above. This list serves as a set of filters through which the search corpus is applied. Mentions of the Ag Census are then searched for within publications meeting these criteria.

ADD TABLE 2 HERE

Next, we compare the degree of overlap across the different search methods, focusing on OpenAlex publications that also overlap with Scopus records. Specifically, we examine whether the OpenAlex full-text search and the OpenAlex seed-corpus approach identified the same publications and journals referencing the Census of Agriculture, or whether each method uncovered distinct sets of works.

Table 3 summarizes the overlap between publications identified through the two OpenAlex search methods, restricted to publications that also appear in Scopus. As reported earlier, 505 publications were identified in both Scopus and OpenAlex using the OpenAlex full-text search (Table 1), while 363 publications were identified using the OpenAlex seed-corpus approach (Table 2). Table 3 specifically shows how many of the 505 full-text search publications were also found in the seed-corpus set. The comparison reveals that 105 publications are shared between the two methods, representing 20.8% of the full-text set and 28.9% of the seed-corpus set. These results suggest that the choice of search strategy meaningfully influences which Scopus-linked publications are recovered in OpenAlex.

ADD TABLE 3 HERE

Table 4 summarizes the overlap between journals identified through the two OpenAlex search methods, restricted to journals linked to publications that also appear in Scopus. As noted previously, the OpenAlex full-text search and seed-corpus approach each identified a set of journals containing publications referencing the Census of Agriculture. Table 4 specifically

shows how many journals were common to both sets. A total of 137 journals were shared between the two methods, representing 55.5% of the full-text set and 49.6% of the seed-corpus set. Among these shared journals, 19 were part of the original list of top journals used to construct the seed corpus.

ADD TABLE 4 HERE

3.2 Journal Coverage

Now that we have compared journal coverage across the two citation databases, we next examine the publications within journals that are indexed in both Scopus and OpenAlex. We report these results for the full-text search approach and the seed-corpus approach in OpenAlex.

3.2.1 Method 1 (Full-Text Search)

Table 5 provides journal-level detail on the overlap between publications indexed in Scopus and OpenAlex, based on the full-text search results in OpenAlex. Each row corresponds to a journal included in the analysis. The set of journals included here matches the group of overlapping journals reported in Table 1—that is, journals where publications were found in both Scopus and OpenAlex.

The table is divided into two sections: overlap statistics and publication counts. The overlap statistics report three measures. The percentage labeled “% Both” indicates the share of a journal’s publications that were found in both Scopus and OpenAlex. “% Scopus” shows the share of publications that appeared only in Scopus, while “% OpenAlex” shows the share of publications that appeared only in OpenAlex. Together, these columns summarize how consistently each journal’s publications are represented across the two databases.

The publication counts section reports the number of overlapping and non-overlapping publications for each journal. “Pubs Both” shows the number of publications found in both Scopus and OpenAlex, while “Pubs Scopus” and “Pubs OpenAlex” show the number of publications found exclusively in one database. The final column, “Total Pubs,” provides the total number of distinct publications associated with each journal across both databases.

Finally, the table also includes each journal’s 2022 Scopus CiteScore to provide additional context on journal prominence.

Reading across a row, the table allows for direct comparison of database coverage at the journal level, highlighting journals where coverage between Scopus and OpenAlex aligns closely and those where substantial gaps exist.

ADD TABLE 5 HERE

To further characterize database coverage, we calculated weighted average CiteScores for the journals analyzed in Table 5. The weighted averages account for both the number of publications associated with each journal and the journal’s 2022 Scopus CiteScore. For Scopus, the weighted average CiteScore, calculated by weighting each journal’s CiteScore by its number of publications found in Scopus (including shared publications), is approximately 12.99. For OpenAlex, the weighted average CiteScore, using the number of publications found in OpenAlex (including shared publications), is slightly higher at 13.23.

These results suggest that, among the overlapping journals, OpenAlex tends to recover a slightly more citation-intensive set of publications compared to Scopus. However, the difference in weighted averages is modest, indicating broadly similar coverage of higher-impact journals across the two databases. To formally test the difference in weighted average CiteScores between Scopus and OpenAlex, we calculated a t-statistic for the difference in means. The resulting t-statistic is approximately -0.15, indicating that the difference between the two weighted averages is not statistically significant. This suggests that, within the set of overlapping journals analyzed, Scopus and OpenAlex recover a similarly citation-intensive set of publications.

3.2.2 Method 2 (Seed Corpus Approach)

We next examine the results obtained using the OpenAlex seed corpus approach.

Table 6 summarizes publication-level overlap statistics for journals identified using the seed corpus approach. As with Table 5, the table is restricted to journals associated with publications that overlap between Scopus and OpenAlex. The overlap statistics show the percentage of each journal’s publications found in both databases (% Both), found only in Scopus (% Scopus), or found only in OpenAlex (% OpenAlex). Publication counts are also reported separately for shared and database-specific publications, along with the total number of publications associated with each journal. Each journal’s 2022 Scopus CiteScore is included to provide additional context on journal prominence.

ADD TABLE 6 HERE

To further compare database coverage under the seed corpus approach, we calculated weighted average CiteScores for Scopus and OpenAlex. The weighted averages account for both the number of publications associated with each journal and the journal’s 2022 Scopus CiteScore. For Scopus, the weighted average CiteScore is approximately 11.90, while for OpenAlex it is higher at approximately 14.10.

A t-statistic for the difference in means was also calculated to assess whether the difference is statistically meaningful. The resulting t-statistic is approximately -2.18, indicating that the difference is statistically significant. These results suggest that, when using the seed corpus approach, OpenAlex recovers a more citation-intensive set of publications compared to Scopus.

3.3 Publication Topics

4 Summary of Findings

This report compares the coverage of publications and journals referencing the Census of Agriculture across Scopus and OpenAlex, using two approaches for identifying relevant OpenAlex publications: a full-text search and a seed corpus approach.

Using the full-text search in OpenAlex, we found relatively limited overlap with Scopus. Only 9.2% of publications and 9.2% of journals referencing the Census of Agriculture appeared in both databases, with Scopus identifying a substantially larger share of relevant works. These results suggest that relying solely on OpenAlex’s full-text search may miss a significant number of dataset mentions.

Applying the seed corpus approach to OpenAlex improved overlap with Scopus and provided a more structured way to capture publications associated with known journals, authors, and topics. However, the percentage of overlapping publications referencing the Census of Agriculture is lower at 6.42% even though there is a slightly higher percentage of shared journals at 10.73%.

Comparing the overlap between the two OpenAlex methods reveals differences in underlying samples. Only 20.8% of full-text search publications were also found in the seed corpus set, and 28.9% of seed corpus publications matched those found in the full-text search. Journal-level overlap was somewhat higher, with 137 journals shared between the two methods (representing approximately 50–55% overlap across the two pools).

Publication-level comparisons disaggregated by journal showed that, under the full-text search approach, OpenAlex and Scopus recovered broadly similar sets of citation-intensive publications. The weighted average CiteScores were 13.23 for OpenAlex and 12.99 for Scopus, with a t-statistic of -0.15, indicating no statistically significant difference. In contrast, under the seed corpus approach, OpenAlex recovered a more citation-intensive set of publications, with a weighted average CiteScore of 14.10 compared to 11.90 for Scopus. The t-statistic of -2.18 indicates that this difference is statistically significant.

It is important to note that the full-text search and seed corpus approaches represent two distinct sampling methods within OpenAlex. The full-text search attempts to identify dataset mentions directly from the body of text available for a subset of publications, while the seed corpus approach relies on pre-selected journals, topics, and authors more likely to reference the Census of Agriculture. As a result, the pools of publications identified by each method are not strictly comparable: they are drawn from different underlying subsets of OpenAlex’s catalog. This context is important for interpreting differences in coverage and citation intensity across the two approaches.

5 Institutional Comparison

In addition to examining dataset mention coverage, the report also evaluates differences in institutional representation across Scopus and OpenAlex. Publication affiliation data are linked to institutional records using IPEDS identifiers to create a harmonized dataset across sources. This allows for assessment of how each citation database represents institutions based on characteristics such as control (public or private), degree level, MSI designation, and geographic location. Special attention is given to coverage of underrepresented institutions and Minority-Serving Institutions (MSIs). This analysis informs broader conversations about equity, transparency, and accountability in research data infrastructure.

Each of the featured citation databases represent some portion of the global research landscape, yet their inclusion criteria and institutional coverage vary in ways that may inform disparities. Our goal is to assess which institutions are represented in each source, with particular attention to coverage of underrepresented and Minority-Serving Institutions (MSIs). By building a harmonized dataset that links IPEDS identifiers to institutional records across Scopus, OpenAlex, and Dimensions, we aim to evaluate how these citation databases include or exclude institutions across institutional characteristics such as control, level, MSI status, and geography. This analysis informs a broader conversation about equity, transparency, and accountability in research data systems.

Step 1: Clean IPEDS and MSI data

In this section, I document the construction and visualization of MSI (Minority-Serving Institution) eligibility trends from 2017 to 2023, as part of the broader effort to compare institutional coverage across Scopus, OpenAlex, and Dimensions. To support that analysis, we needed a clean, panel-form dataset of U.S. higher education institutions, including consistent MSI designations over time. I compiled and cleaned data from multiple sources—the MSI Data Project (Nguyen et al., 2023) for 2017–2021 and Rutgers CMSI lists for 2022–2023—and merged these with IPEDS institutional data, filtered to include only 2- and 4-year institutions in the 50 U.S. states. I addressed inconsistencies in eligibility labels, resolved duplicates, and created summary measures of MSI eligibility by year. The resulting visualization highlights both the number and percent of institutions designated as MSIs over time, with a sharp increase observed in 2022. The accompanying plot and source code are included for transparency. All additional details are available in the IPEDS³ and MSI⁴ Appendices.

³[IPEDS appendix available here](#)

⁴[MSI appendix available here](#)

Note: Data sources differ across years.
 2017–2021: MSI Data Project (Nguyen et al., 2023); 2022–2023: Rutgers CMSI
 Filters: Only 2- or 4-year institutions in the 50 US states. Enrollment > 0.
 MSI Types: ANNHSI, AANAPISI, HSI, HBCU, NASNTI, PBI, TCCU.
 Total Institutions per Year:
 2017 = 5326, 2018 = 5129, 2019 = 4878, 2020 = 4788, 2021 = 4726, 2022 = 4706, 2023 = 4629
